Hotel Reservation Analysis

Answering 15 business questions with SQL on IBM Db2

Damaris

What does a hotel manager want to know?

Who is booking, when, what they choose and what they pay. I used SQL to turn a table of reservations into answers a manager can act on.

Tools: SQL, IBM Db2

700

reservations analysed

1,316

adult guests

69

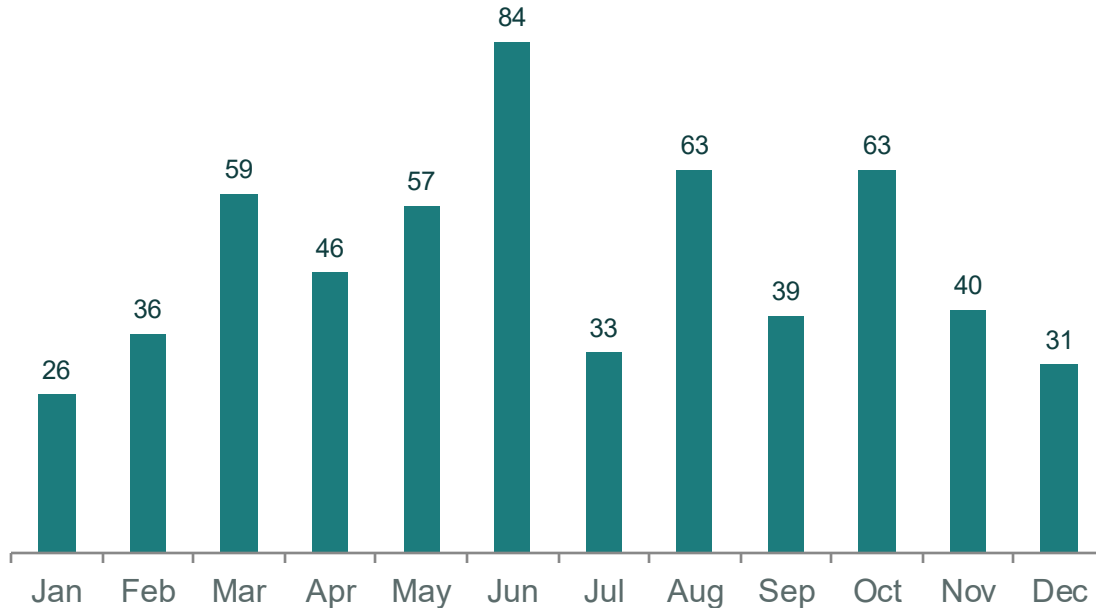

child guests

15

questions answered

Bookings peak in June and dip in winter

Reservations by arrival month, 2018

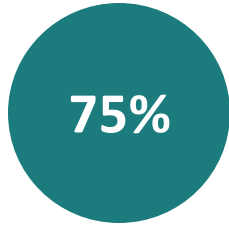

So what?

June is the busiest month with 84 arrivals; January is the quietest with 26. 577 of the 700 reservations arrive in 2018.

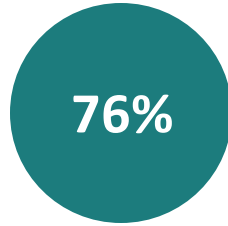

Staffing and promotions can follow this rhythm.

Most guests choose the same options

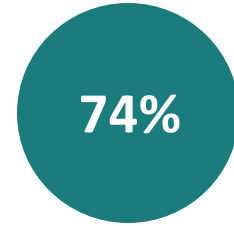

Meal Plan 1

527 of 700 reservations

Room_Type 1

534 of 700 reservations

Online channel

518 of 700 reservations

Most popular meal plan, room type and market segment each cover about three quarters of bookings, so a few core products drive demand.

How guests stay

54.7%

of reservations include weekend
nights (383 of 700)

0 to 443 days

Booking lead time ranges from same-day to well over a year ahead.

5% children

69 children against 1,316 adults, so family travel is a small segment.

Families pay noticeably more per room

So what?

Bookings with children average about 145 per room, roughly 29% above the online average of 112. Online is also the segment with the highest average price.

What I would recommend

1

Protect the core

Keep Room_Type 1, Meal Plan 1 and online sales front and centre.

2

Build family offers

Families pay more, so package weekend stays for them.

3

Fill the quiet months

Run promotions in January, February and July.

Limitations and next steps

- Results come from a sample of 700 reservations.
- Next: cancellation rate by segment and lead time.
- Next: a Power BI dashboard on these results.
